Abstract

Using new experimental data, we have calculated the contribution to the anomalous magnetic moment of the muon from the $\pi^0\gamma$ and $\eta\gamma$ intermediate states in the vacuum polarization with high precision: $a_\mu(\pi^0\gamma) + a_\mu(\eta\gamma) = (54.7 \pm 1.5) \times 10^{-11}$. We have also found the small contribution from $e^+e^-\pi^0$, $e^+e^-\eta$ and $\mu^+\mu^-\pi^0$ intermediate states equal to 0.5×10^{-11} .

New experimental data [1–3] allows to calculate contribution to the anomalous magnetic moment of the muon $a_\mu \equiv \frac{g_\mu - 2}{2}$ from the $\pi^0\gamma$ and $\eta\gamma$ intermediate states in the vacuum polarization with high precision. We have also found the contribution from $e^+e^-\pi^0$, $e^+e^-\eta$ and $\mu^+\mu^-\pi^0$ intermediate states.

The contribution to a_μ from the arbitrary intermediate state X (hadrons, hadrons+ γ , etc.) in the vacuum polarization can be obtained via the dispersion integral

$$a_\mu = \left(\frac{\alpha m_\mu}{3\pi}\right)^2 \int \frac{ds}{s^2} K(s) R(s). \quad (1)$$

$$R(s) \equiv \frac{\sigma(e^+e^- \rightarrow X)}{\sigma(e^+e^- \rightarrow \mu^+\mu^-)}, \quad \sigma(e^+e^- \rightarrow \mu^+\mu^-) \equiv \frac{4\pi\alpha^2}{3s}.$$

$$\begin{aligned} K(s > 4m_\mu^2) &= \frac{3s}{m_\mu^2} \left\{ x^2 \left(1 - \frac{x^2}{2}\right) + (1+x)^2 \left(1 + \frac{1}{x^2}\right) \left[\ln(1+x) - x + \frac{x^2}{2} \right] + \frac{1+x}{1-x} x^2 \ln(x) \right\} = \\ &= \frac{3}{a^3} \left(16(a-2) \ln \frac{a}{4} - 2a(8-a) - 8(a^2 - 8a + 8) \frac{\operatorname{arctanh}(\sqrt{1-a})}{\sqrt{1-a}} \right), \\ x &= \frac{1 - \sqrt{1 - \frac{4m_\mu^2}{s}}}{1 + \sqrt{1 - \frac{4m_\mu^2}{s}}}, \quad a = \frac{4m_\mu^2}{s}. \end{aligned}$$

$$K(s < 4m_\mu^2) = \frac{3}{a^3} \left(16(a-2) \ln \frac{a}{4} - 2a(8-a) - 8(a^2 - 8a + 8) \frac{\operatorname{arctan}(\sqrt{a-1})}{\sqrt{a-1}} \right).$$

Evaluating integral (1) with the trapezoidal rule for the experimental data from SND [1,2], see Fig. 1(a), we found the contribution of $\pi^0\gamma$:

$$a_\mu(\pi^0\gamma) = (46.2 \pm .6 \pm 1.3) \times 10^{-11}, \quad 600 \text{ MeV} < \sqrt{s} < 1039 \text{ MeV}. \quad (2)$$

The first error is statistical, the second is systematic. For the energy region $\sqrt{s} < 600$ MeV we used theoretical formula for the cross-section:

$$\sigma(e^+e^- \rightarrow \pi^0\gamma) = \frac{8\alpha f^2}{3} \left(1 - \frac{m_{\pi^0}^2}{s}\right)^3 \frac{1}{\left(1 - \frac{s}{m_\omega^2}\right)^2}, \quad (3)$$

where $f^2 = \frac{\pi}{m_{\pi^0}^3} \Gamma_{\pi^0 \rightarrow \gamma\gamma} \cong 10^{-11}/\text{MeV}^2$ according to [4]. Eq. (3) has been written in the approximation

$$\Gamma_\rho = \Gamma_\omega = 0, \quad m_\rho - m_\omega = 0. \quad (4)$$

The $\gamma^* \rightarrow \pi^0\gamma$ amplitude is normalized on the $\pi^0 \rightarrow \gamma\gamma$ one at $s = 0$. The result is

$$a_\mu(\pi^0\gamma) = 1.3 \times 10^{-11}, \quad \sqrt{s} < 600 \text{ MeV}. \quad (5)$$

Note that the region $\sqrt{s} < 2m_\mu$ gives the negligible contribution 2×10^{-13} .

We neglect the small errors dealing with the experimental error in the width $\Gamma_{\pi^0 \rightarrow \gamma\gamma}$ (7%) and the approximation (4) (1.5%).

The Eq. (3) agrees with the data in the energy region $\sqrt{s} < 700$ MeV, at higher energies the approximation (4) does not work carefully, see Fig. 1(b).

If we use the point-like model, as in [5], we will get Eq. (3) without factor $\left(1 - \frac{s}{m_\omega^2}\right)^{-2}$. This formula predicts the contribution from low energies several times less than (5), see also Fig. 1(b).

Treating the data from CMD-2 [3] in the same way, we get contribution of $\eta\gamma$:

$$a_\mu(\eta\gamma) = (7.1 \pm .2 \pm .3) \times 10^{-11}, \quad 720 \text{ MeV} < \sqrt{s} < 1040 \text{ MeV}. \quad (6)$$

According to the quark model (and the model of vector dominance also), the energy region $\sqrt{s} < 720$ MeV is dominated by the ρ -resonance, hence $\sigma(e^+e^- \rightarrow \eta\gamma) \cong \sigma(e^+e^- \rightarrow \rho \rightarrow \eta\gamma)$. So we change Eq. (3) according to this fact, take into account the ρ width and get the small contribution:

$$a_\mu(\eta\gamma) = .1 \times 10^{-11}, \quad \sqrt{s} < 720 \text{ MeV}, \quad (7)$$

Summing (2), (5), (6) and (7), we can write

$$a_\mu(\pi^0\gamma) + a_\mu(\eta\gamma) = (54.7 \pm .6 \pm 1.4) \times 10^{-11}, \quad (8)$$

where statistical and systematic errors are separately added in quadrature. In Table 1 we present our results with statistical and systematic errors added in quadrature. Comparing Eq. (8) with the analogous calculation in [5] (see Table 1), one can see that our result is 27% more and the error is 2.5 times less. The contribution (8) accounts for 1.37 of the projected error of the E821 experiment at Brookhaven National Laboratory (40×10^{-11}) or 36% of the reached accuracy (150×10^{-11} [6]).

We can also take into account the intermediate state $\pi^0 e^+ e^-$, using the obvious relation

$$\sigma(e^+e^- \rightarrow \pi^0 e^+ e^-, s) = \frac{2}{\pi} \int_{2m_e}^{\sqrt{s}-m_{\pi^0}} \frac{dm}{m^2} \Gamma_{\gamma^* \rightarrow e^+ e^-}(m) \sigma(e^+e^- \rightarrow \pi^0 \gamma^*, s, m), \quad (9)$$

where m is the invariant mass of the e^+e^- system, $\Gamma_{\gamma^* \rightarrow e^+ e^-}(m) = (1/2)\alpha\beta_e m(1 - \beta_e^2/3)$, $\beta_e = \sqrt{1 - 4m_e^2/m^2}$, $\sigma(e^+e^- \rightarrow \pi^0 \gamma^*, s, m) = \left(p(m)/p(0)\right)^3 \sigma(e^+e^- \rightarrow \pi^0 \gamma, s)$, $p(m) = (\sqrt{s}/2)\sqrt{(1 - (m_{\pi^0} + m)^2/s)(1 - (m_{\pi^0} - m)^2/s)}$ is the momentum of γ^* in s.c.m.

In the same way we can calculate $a_\mu(\mu^+ \mu^- \pi^0)$ and $a_\mu(e^+ e^- \eta)$. The result is

$$a_\mu(e^+ e^- \pi^0) + a_\mu(\mu^+ \mu^- \pi^0) + a_\mu(e^+ e^- \eta) = (.4 + .026 + .057) \times 10^{-11} = .5 \times 10^{-11}. \quad (10)$$

Note that if $m \gtrsim m_\rho$ we have the effect of the excitation of resonances in the reaction $e^+e^- \rightarrow \pi^0(\rho, \omega) \rightarrow \pi^0 e^+ e^-$. However this effect increases the final result (10) less than by 10% because of the factor $(p(m)/p(0))^3$, which suppresses the high m . So we ignore this correction. We also neglect $a_\mu(\mu^+ \mu^- \eta) = 2 \times 10^{-14}$.

As it was noted in [5] and [7], it is necessary to take into account also

$$a_\mu(hadrons + \gamma, rest) = a_\mu(\pi^+ \pi^- \gamma) + a_\mu(\pi^0 \pi^0 \gamma) + a_\mu(hadrons + \gamma, s > 1.2 \text{ GeV}^2).$$

We take $a_\mu(\pi^+\pi^-\gamma) = (38.6 \pm 1.0) \times 10^{-11}$ from [7] (see also [5]), $a_\mu(\pi^0\pi^0\gamma) + a_\mu(hadrons + \gamma, s > 1.2 \text{ GeV}^2) = (4 \pm 1) \times 10^{-11}$ from [5]. Adding this to (8), we get

$$a_\mu(hadrons + \gamma, total) = (97.3 \pm 2.1) \times 10^{-11}. \quad (11)$$

The contribution (11) accounts for 2.43 of the projected error of the E821 experiment or 65% of the reached accuracy.

In fact, the errors in (8) and (11) are negligible for any imaginable $(g-2)_\mu$ measurement in near future.
